CareerConnect - AI Usage Log

Name: Matthew Lazarov
Sprint: 2

Entry 1

Entry number: 1
Date: September 27 to October 2026
AI tool/model: ChatGPT (OpenAI), GPT-6
Task ID/Title: Resume Management — Frontend Implementation

Purpose of AI Use: Frontend development and implementation guidance. Understand how to build the resume management interface and connect its components to the existing CareerConnect application.

Chat Link or Prompt/Response: See Appendix, Entry 1.

AI-Suggested Content: ChatGPT helped with the structure and styling of the resume interface using Next.js, React, TypeScript, and Tailwind CSS. The guidance covered the resume upload interface, file selection, upload states, displaying uploaded resumes, and organizing the UI into reusable components. As the feature evolved, the guidance also covered managing multiple resumes, including active and archived resume views, pagination, and actions for downloading, renaming, replacing, archiving, unarchiving, and deleting resumes.

Validation: Reviewed the suggested UI against the existing application structure and tested the implemented functionality during development. The resume interface was integrated with the existing application rather than treated as an independent mockup. PDF upload restrictions and the display of resume metadata were considered as part of the implementation.

Decision: Used as a debugging and learning resource. I implemented the resume management feature myself and used ChatGPT to understand technical concepts, investigate issues, and evaluate possible solutions.

Reflection: Working through the interface helped me understand how frontend components, user interactions, and application state work together. It also showed the importance of handling loading states and errors rather than implementing only the visual appearance.

Responsible Person: Matthew Lazarov

Entry 2

Entry number: 2
Date: October 2026

AI tool/model: ChatGPT (OpenAI), GPT-6
Task ID/Title: Multiple Resume Management — Backend and Supabase Storage Integration

Purpose of AI Use: Backend integration and troubleshooting. Understand how uploaded resume files and their database records should be managed throughout the application.

Chat Link or Prompt/Response: See Appendix, Entry 2.

AI-Suggested Content: ChatGPT helped explain the relationship between Supabase Storage and PostgreSQL metadata. The guidance covered storing resume files in the resumes bucket while keeping their identifiers, filenames, storage paths, upload timestamps, and archive status in the resumes table. It also helped clarify how frontend actions should correspond to backend operations, including updating resume metadata and retrieving the correct file for download or replacement.

The guidance included using the archive timestamp to distinguish active resumes from archived ones and organizing the queries used to display the corresponding lists.

Validation: Checked the database structure and the frontend operations against the existing Supabase setup. The implementation used the resume record's storage path to identify the corresponding file. The archive and unarchive functionality also required an appropriate database update policy, which was addressed after an authorization issue was encountered.

Decision: Used as a debugging and learning resource. I implemented the resume-management integration myself and used ChatGPT to understand the relationship between file storage and database records, investigate permission issues, and evaluate possible solutions.

Reflection: I learned that uploading a file and managing its database record are separate operations. Both must work correctly for features such as replacing, archiving, and deleting resumes to behave consistently.

Responsible Person: Matthew Lazarov

Entry 3

Entry number: 3
Date: October 2026
AI tool/model: ChatGPT (OpenAI), GPT-6
Task ID/Title: Supabase Database Schema, Row-Level Security, and Migration Management

Purpose of AI Use: Database development and troubleshooting. Understand how schema changes, security policies, and migration files support the frontend and backend functionality of CareerConnect.

Chat Link or Prompt/Response: See Appendix, Entry 3.

AI-Suggested Content: ChatGPT helped explain PostgreSQL tables, foreign-key relationships, Row-Level Security (RLS), and the relationship between the live Supabase database and the SQL migration files maintained in the repository. The guidance covered user ownership of records, access to resume data, and the distinction between database operations and file-storage policies.

It also helped me understand why database changes should be represented by focused migration files and why unrelated changes should not be included in a migration for a specific feature.

Validation: Reviewed the database changes against the application's existing schema and tested the affected functionality during development. One issue involved archiving resumes: the existing policies did not permit the required update operation. This helped identify the need for an appropriate update policy. I also worked with the team's workflow of managing database changes through the Supabase Dashboard and committing the relevant SQL migration files to Git.

Decision: Used as a debugging and learning resource. I handled the database and migration work myself, using ChatGPT to understand schema changes, investigate RLS issues, and evaluate migration practices against the existing project workflow.

Reflection: This work improved my understanding of how the live database, application queries, RLS policies, and version-controlled migration files fit together. I also learned that a feature can fail even when its frontend logic is correct if the database does not authorize the required operation.

Responsible Person: Matthew Lazarov

Entry 4

Entry number: 4
Date: October 2026
AI tool/model: ChatGPT (OpenAI), GPT-6
Task ID/Title: Job Application Submission — Resume Relationships and Backend Validation

Purpose of AI Use: Backend design and data integrity. Understand how job applications relate to job postings, applicant profiles, and uploaded resumes.

Chat Link or Prompt/Response: See Appendix, Entry 4.

AI-Suggested Content: ChatGPT helped explain the relationships between the applications, jobs, profiles, and resumes tables. It clarified the purpose of fields such as applicant_id, job_id, and resume_id and how related records can be retrieved through Supabase queries.

The guidance also identified an important data-integrity requirement: an application should not be able to reference a resume belonging to another user. A foreign key can verify that a resume

record exists, but does not, by itself, establish that the resume belongs to the applicant submitting the application.

The discussion covered using backend validation and database security rules to enforce this relationship.

Validation: Compared the proposed relationships and validation approach with the project's schema and application submission requirements. The project uses a database validation trigger for application resumes, named validate_application_resume, to validate the resume relationship. The implementation needed to remain consistent with the existing application submission flow and database constraints.

Decision: Used as a debugging and learning resource. I worked on the application data relationships myself and used ChatGPT to understand the schema, investigate potential ownership and validation issues, and evaluate possible solutions.

Reflection: I learned that validating submitted data requires more than checking whether a record exists. The application must also enforce ownership and maintain consistent relationships between users, job postings, and resumes.

Responsible Person: Matthew Lazarov

Entry 5

Entry number: 5
Date: October 2026
AI tool/model: ChatGPT (OpenAI), GPT-6
Task ID/Title: Application Status Interface

Purpose of AI Use: Frontend development and integration. Understand how to organize the application status interface and connect its presentation to the application's existing data.

Chat Link or Prompt/Response: See Appendix, Entry 5.

AI-Suggested Content: ChatGPT helped with implementation guidance for displaying job applications according to their statuses. The discussion covered organizing the interface into status categories, displaying application information, and keeping the UI consistent with the rest of the CareerConnect application.

The implementation involved the Application Status feature and its dedicated development branch, feature/ApplicationStatusUI. The interface was designed around the project's application statuses: In Progress, Interviews, Offers, and Rejected.

Validation: Reviewed the implementation against the expected application workflow and existing project structure. The UI needed to display the relevant application information without introducing status categories that were inconsistent with the application's data model.

Decision: Used as a debugging and learning resource. I worked on the application status interface myself and used ChatGPT to clarify the relationship between the UI, status values, and existing application data.

Reflection: I learned how frontend organization can make application information easier to navigate while remaining dependent on the underlying database records and status values. Keeping the interface aligned with the data model also helps avoid inconsistencies between what users see and what the system stores.

Responsible Person: Matthew Lazarov

Entry 6

Entry number: 6
Date: October 2026
AI tool/model: ChatGPT (OpenAI), GPT-6
Task ID/Title: Public Profile Data and Database Synchronization

Purpose of AI Use: Database design and integration. Understand how profile information can be made available to the appropriate parts of the application without exposing private account information unnecessarily.

Chat Link or Prompt/Response: See Appendix, Entry 6.

AI-Suggested Content: ChatGPT helped explain the purpose of a public profile data structure and how database triggers can keep selected profile information synchronized. The project uses a profiles_public table, with a trigger that synchronizes profiles.full_name to profiles_public.public_name for displaying names in relevant parts of the application.

The discussion also covered the importance of separating information intended for public or recruiter-facing display from private profile information and enforcing access through database policies.

Validation: Considered the proposed structure alongside the existing profiles table, recruiter-facing functionality, and database security requirements. The public profile structure and synchronization trigger were used to support the application's display of profile names without requiring every feature to access the full private profile record.

Decision: Used as a debugging and learning resource. I worked on the profile-data integration myself and used ChatGPT to understand database triggers, synchronization, and access restrictions, and to evaluate possible solutions.

Reflection: I gained a better understanding of database triggers and why applications sometimes need a separate structure for information intended to be displayed to other users. I also learned that data visibility should be considered at the database level, rather than relying exclusively on frontend restrictions.

Responsible Person: Matthew Lazarov

Appendix

Entry 1 — Resume Management Frontend

Prompt summary: Help implement the resume management interface within the existing Next.js and React application.

Response summary: ChatGPT provided implementation guidance for the UI structure, upload controls, resume listings, user actions, and component styling. Later discussions covered active and archived resume views and the controls needed to manage multiple resumes.

Entry 2 — Resume Storage and Backend Operations

Prompt summary: Explain how to connect the resume interface to Supabase Storage and the resumes database table.

Response summary: ChatGPT explained how file paths and metadata should be stored, how the frontend can perform resume operations, and how archive status can be used to separate active and archived records. Troubleshooting also covered the database permissions required for update operations.

Entry 3 — Database Policies and Migrations

Prompt summary: Help me understand Supabase RLS policies, database changes, and how to maintain migration files in the project repository.

Response summary: ChatGPT explained table ownership, update permissions, foreign-key relationships, and migration-file organization. It helped me understand why changes in the live database need to be represented appropriately in the repository and why unrelated SQL changes should be excluded from feature migrations.

Entry 4 — Job Application Data Relationships

Prompt summary: Explain how applications should reference job postings, applicants, and resumes, and how the system should validate the selected resume.

Response summary: ChatGPT explained the relationships between the database tables and the limitations of relying on foreign keys alone to enforce resume ownership. The discussion covered database-side validation and the importance of protecting application data.

Entry 5 — Application Status UI

Prompt summary: Help organize the application status interface and understand how to present applications according to their current status.

Response summary: ChatGPT provided guidance on the interface structure and the relationship between status categories and the underlying application records. The suggestions were adapted to the existing CareerConnect implementation.

Entry 6 — Public Profile Synchronization

Prompt summary: Explain how to synchronize selected profile information for recruiter-facing functionality while maintaining appropriate database access restrictions.

Response summary: ChatGPT helped clarify the purpose of a public profile table, a synchronization trigger, and the separation between display information and private profile data.
